2022 IEEE 7th International Conference on Information Technology and Digital Applications (ICITDA) | 978-1-6654-6136-8/22/$31.00 ©2022 IEEE | DOI: 10.1109/ICITDA55840.2022.9971323

***Abstract*—As we transitioned to the new normal, most academic institutions implemented a comprehensive work-from-home strategy during the height of the pandemic. An established research model will be used to evaluate an LMS as a blended workplace, with the goal of establishing a reference point. Likert scale with indication of 1 as strongly disagree to 7 as strongly agree, the questionnaire survey was designed in accordance with the established research model of UTAUT2 by Venkatesh. Structural Equation Modeling and Partial Least Squares (PLS) were used to analyze the data in this study. This study assessed the reliability and validity of the proposed hypotheses using structural model, measurement model, and moderator analysis. Other confirmatory analyses were performed to assess the developed hypothesis, including goodness of fit, goodness of model, collinearity, bootstrapping, and its predictive power. It was found out that the factors included in the proposed research framework of the study had a positive and significant impact on the use of the LMS as a blended workplace application in the study. As a result, it is recommended that it be used for university-wide implementation. A learning management system (LMS), specifically Moodle, can be extremely beneficial for educational institutions that are applying for international standard certification or program accreditation. It can assist with maintaining administrative tasks, submission, reviewing, approval, and monitoring of required documents.**

***Index Terms*—PLS, SEM, LMS, Blended Workplace, Quality Assurance**

I. Introduction

As we shifted to the new normal, the majority of academic institutions embraced a complete work-from-home strategy during the pandemic's peak. Many transactions are now gradually reopening and instituting elaborate safety precautions and distance-based design to help safeguard everyone from infection. The ability to be adaptable is critical for academic institutions to thrive during these ongoing changes. The pandemic is driving digital transformation in many organizations.

A. Impact of COVID-19 on Higher Education's Quality Assurance

The number of verified COVID-19 cases recorded in an online report by the Department of Health indicates that Higher Education Institutions (HEIs) have been affected by the outbreak. [1] During the height of the pandemic, academic institutions in the Philippines struggled to provide services to students, stakeholders, and other clients. As a result, all administrative activities in the academe have moved from residential to virtual. Despite the COVID-19 issues, educational countermeasures are being implemented to keep students engaged. [2]. Instructional paradigms were also substantially influenced. Some of the Philippines' HEIs managed to operate online classes using Google's free services. The use of a Learning Management System, or LMS, is an effective way to provide students with access to online instruction. Partido State University (ParSU), with seven (7) campuses in Camarines Sur, Philippines, is a Level 3 Smart Campus that has successfully implemented flexible learning management using Moodle as its official LMS. For universities that are considered Smart Campus, Levels 2a, 2b, and 3, these HEIs are ready to implement highly customized LMS due to their ability to collect, analyze, personalized, and sustained culture and performance that promotes innovation and growth in smart learning and teaching. [3], [4] In 2021, there is a significant increase of Moodle-based course delivery. Hence, HEIs had difficulties not only with delivering courses in different modes (online, modular, and blended) during the pandemic, but also with keeping up with work instructions, but most especially on quality assurance, administrative tasks, monitoring the submission of required reports, and making sure that targets are always met. This paper would like to explore the possibility of using an LMS as an alternative system for collecting documents using web technology to help with administrative tasks and meet goals for quality assurance and program accreditations during and post-pandemic situations. Motivated by these ideas and developments, this paper seeks to answer the research question: How an LMS can be utilized to support quality assurance for different programs despite the pandemic? This study will not examine the usage of Moodle as an LMS for course delivery; rather, the LMS will be utilized as a tool for continuous administrative duties in a blended workplace.

B. Maintaining Quality Education in the Pandemic

Program accreditation and international survey audits are required in the academe. As proof of excellent service, regulatory bodies require them to maintain SUC levels and certification. These programs ensure HEIs achieve excellence standards. However, poor documentation is a significant cause of audit failure. [5]. This issue arises from inefficient document organization, storage, and management. Even program accreditation and international survey audits are conducted

remotely, so an immediate quick fix is programmed. The challenge is the Philippines' policy requiring everybody to observe Work from Home (WFH). Due to constraints, submitting relevant documentation as proof of compliance is compromised. This study will be beneficial in the academe since annual surveillance visits and remote video-conferencing audits require softcopies of all documents. LMS can help an institution organize and maintain needed documents, which are vital for zero non-compliance and certifications. Since ParSU is already utilizing an LMS as alternative blended workplace environment, user behavior is a factor that affects acceptability of the technology being offered. Use behavior depends on the direct influence of facilitating conditions and behavioral intention. Mediating factors such as age, gender and experience are great contributors to determine how well the technology is being embraced by the organization. There are similar research that have been published on the utilization of LMS as a blended learning environment, but not as a blended workplace.

C. Blended Workplace

We have witnessed different levels of technology adoption, and a variety of tools and platforms, many of which have been around and have become our lifeline. As we cautiously and optimistically progress towards the reduction of constraints imposed by the pandemic, a hybrid and blended working model is emerging. In India, there are companies that had provision for WFH policy for its employees, but for them it was more of an option rather a choice. This is because of their conviction that the expansion of remote culture, especially in remote work, inhibits creative spark when we engage with actual people in proximity as opposed to their virtual bodies. [6] The need to demonstrate resilience and adaptability is of utmost importance in the academe, particularly when it comes to adopting new technologies with or without a pandemic. These transitions were implemented almost overnight and executed within a very short period. These working styles, habits, and delivery modes are becoming more blended. The physical location of employees is an element that influences the blended workplace. Some employees will work full or part time in the office, while the majority will continue to work from home. Blended work combines the benefits of both physical and virtual work environments, making it possible for individuals to engage in hybrid modes of work in which they move freely between virtual and physical places. [7] During the pandemic, performing administrative responsibilities, committee memberships, and counterparts for quality assurance activities is a formidable obstacle. Therefore, an expedient solution was imposed in resolving these weaknesses and maintain quality despite the emergence of COVID-19.

D. Potential Use of LMS in Quality Assurance

We can use MOODLE's power and robustness as an LMS to establish an alternate platform for an online document repository. There are no publications and scholarly works that examine this methodology's potential. No other program in the same context employs MOODLE's capabilities. This study will investigate MOODLE LMS functions for documenting information. This will also investigate making MOODLE a tool for blended workplaces, establish acceptable functions, and evaluate its effectiveness. This will allow other HEIs in the country to use MOODLE LMS to manage their documented information.

II. THEORETICAL RESEARCH MODEL

The Technology Acceptance Model (TAM) is one of the most influential model by Fred Davis and Richard Bagozzi. [8], [9] Many of the attitude measures included in Theory of Reasoned Action (TRA) are largely replaced by TAM's two measures of technological acceptance: ease of use and usefulness. [10] The TAM was developed specifically for use in the context of information systems, with the goal of predicting how employees will accept and make use of new information technology on the job. [11] The TAM was developed specifically for use in the context of information systems, with the goal of predicting how employees will accept and make use of new information technology on the job. [11], [12], [13] The UTAUT is extended in Venkatesh's work so that it may determine not only acceptance but also application of technology in the context of consumers. [19] As a result of these enhancements to the model, the researchers decided to choose UTAUT2 as the research model to use to investigate the research question.

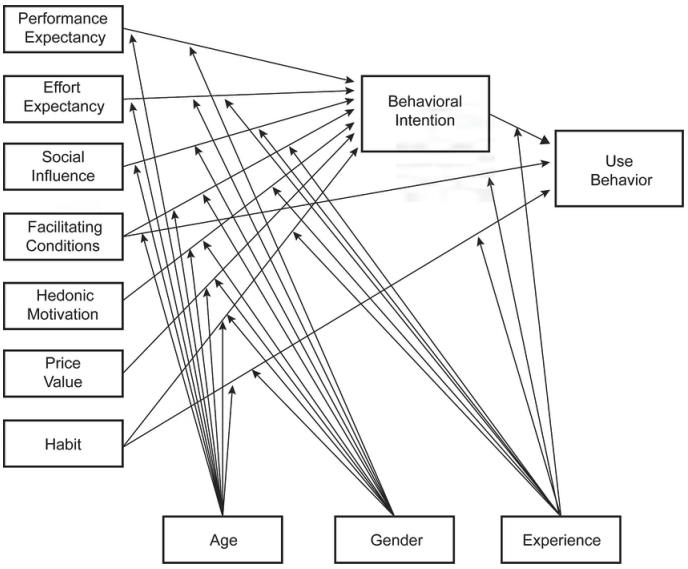

Fig. 1. UTAUT2 Model

Figure 1 presents UTAUT2 model by Venkatesh [13], [15], [16] that is adopted in this study as the theoretical framework to examine the acceptability of using the PSU myLMS as a blended workplace. Considering that numerous acceptance models that are presented and widely used in the research field the model introduced by Venkatesh, UTAUT2 [14], outperformed these models. Moreover, including moderating

Authorized licensed use limited to: Technological Inst of the Philippines. Downloaded on May 23,2023 at 09:58:04 UTC from IEEE Xplore. Restrictions apply.

variables such as age, gender, and experience are suited in this type of research endeavor.

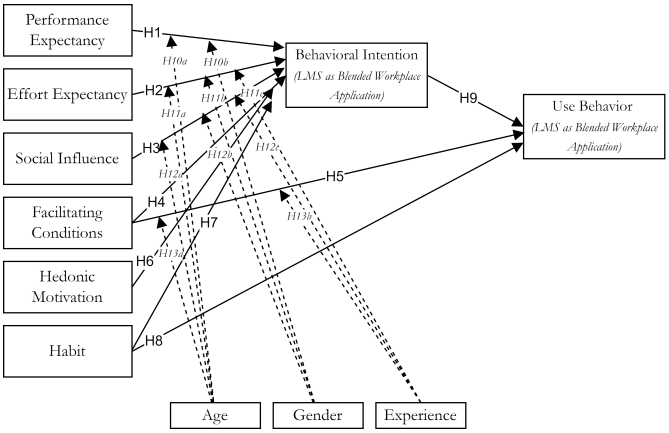

Fig. 2. Theoretical Research Model

A. Definition of Constructs and its hypothesis

To establish the model and test its corresponding constructs, the following were used to define each hypothesis.

1) Performance Expectancy (PE): The degree to which an individual believes that making use of the system will assist them in becoming more effective in their work. [11]. Previous studies have indicated that an individual's level of performance expectation is a strong predictor of their intention to behave in certain manner. [11]

Hypothesis 1 (H1). *Performance expectancy directly and positively affects behavioral intentions of users to use the web application.*

2) Effort Expectancy (EE): The extent of ease associated with using the system is defined as effort expectancy. Previous research indicates that a latent variable related to effort expectancy was important in predicting a person's willingness to adopt new technology. [11]

Hypothesis 2 (H2). *EE positively and directly affects behavioral intentions of users to use the web application.*

3) Social Influence (SI): It refers to how strongly someone believes the individual should use the new system. In cases of voluntary use, the social influence factor has no effect.

Hypothesis 3 (H3). *SI directly and positively affects behavioral intentions of users to use the web application.*

4) Facilitating Conditions (FC): Facilitating conditions are a concept that shows how much control a person thinks they have over their behavior.

Hypothesis 4 (H4). *FC directly and positively affect behavioral intentions of users to use the web application.*

Hypothesis 5 (H5). *FC directly and positively affect the use behavior of user to the web application.*

5) Hedonic Motivation (HM): We define hedonic motivation as a feeling of pleasure or happiness from using a new technology.

Hypothesis 6 (H6). *HM will have a significant influence on behavioral intention to use the web application*

6) Habit (HB): Venkatesh et al. [11] modeled habit as having both direct and indirect effects through the use of behavioral intention.

Hypothesis 7 (H7). *HB directly and positively affects the behavioral intentions of users to use the web application.*

Hypothesis 8 (H8). *HB directly and positively affects the use behavior of user to the web application.*

7) Behavioral Intention (BI): Based on primary theory for all the intention models discussed above we expect that behavioral intention would be best forecaster of actual behavior.

Hypothesis 9 (H9). *BI will have a significant and positive influence on use behavior of user to the web application*

The moderating effects of gender, age, and experience were analyzed in this paper. In this paper, it adopted the research model of Venkatesh, et. Al presented in Figure 2, with its moderating factors. Hence, the moderating factor, experience, is not defined as how long users have been using the technology because all faculty members are required to use the LMS. Experience is divided into two: synchronous and asynchronous. This it to determine that these experiences as moderators will influence the latent variables. To determine the experience, the researcher gets the average of the synchronous and asynchronous interaction of users. Given the inconsistency of the relationships revealed in the preceding findings, it is necessary to determine whether these moderators have a significant contingent effect on the association of the identified indirect and direct variables. In light of the foregoing discussion, the following hypotheses have been proposed:

Hypothesis 10a (H10a). PExAge — *BI User's age has significant effect on performance expectancy*

Hypothesis 10b (H10b). PExGender — *BI User's gender has significant effect on performance expectancy*

Hypothesis 11a (H11a). EExAge — *BI User's age has significant effect on effort expectancy*

Hypothesis 11b (H11b). EExGender — *BI User's gender has significant effect on effort expectancy*

Hypothesis 11c (H11c). EExExp — *BI User's experience has significant effect on effort expectancy*

Hypothesis 12a (H12a). SIxAge — *BI User's age has significant effect on social influence*

Hypothesis 12b (H12b). SIxGender — *BI User's gender has significant effect on social influence*

Hypothesis 12c (H12c). SIxExperience — *BI User's experience has significant effect on social influence*

Hypothesis 13a (H13a). FCxAge — *UB User's age has significant effect on facilitating conditions*

Hypothesis 13b (H13b). FCxExp — *UB User's age has significant effect on facilitating conditions*

III. METHODOLOGY

A. Technology studied

Partido State University (ParSU) has various in-house developed information systems, including those for admissions and enrollment, cashiering, and human resource administration. Additionally, ParSU has contracted with service partners to facilitate its online admissions and enrollment processes. ParSU then established a Virtual Learning Environment based on the MOODLE architecture during the pandemic's height. The institution's Learning Management System (LMS) capabilities enable it to overcome problems connected with the rapid transition from face-to-face or residential education to flexible learning. The Commission on Higher Education visited and assessed the implementation of the aforementioned technologies in order to identify its readiness to provide high-quality education even in the event of a pandemic. With this development, the College of Arts and Sciences (CAS) in the main campus devised the LMS in creating a blended workplace that would allow its faculty members to continue its administrative works on whatever work arrangements is implemented. CAS managed to improve its workflow by removing threads from emails, submission of documents to messaging platforms, or resolving to other alternatives ways of maintaining and continuing the services in the college.

B. Participants, Instrument Development, and Procedure

1) Participants: All faculty members of the college including those who have administrative functions such as the Dean, Program Directors, Administrative Aides are involved in the paper. The main reason of this is to check the acceptability of the faculty members based on their perceived usefulness and ease of use of the technology. Considering also that the great toil will be handled by the Office of the College Dean, it is also identified that the perceived usefulness and ease of use of these people are much likely higher than the faculty members'. There are 58 faculty members including the college secretariats in the College of Arts and Sciences.

2) Instrument Development: Based on Venkatesh's established research model of UTAUT2, the questionnaire survey was designed using a 7-point Likert Scale ranging from 1 (strongly disagree) to 7 (strongly agree). There are 38 items and 8 constructs, including PE (4 items), EE (4 items), SI (3 items), FC (4 items), HM (3 items), HB (4 items), BI (3 items), and UB (10 items). All questions were adopted from the original manuscript of Venkatesh [19] All questions were in English and was distributed using Microsoft's Form using this link: *https://forms.office.com/r/EEbELXbYG4.*

C. Procedure

The study used the descriptive-quantitative research design. Data were collected on the second semester of the academic year 2021-2022, using the UTAUT2 questionnaire [11]. Under less than three weeks' time, utilizing Microsoft's Form Application to collect responses, the survey obtained a rate of 97 percent or 51 responses achieving the optimal number of respondents. The survey has three parts. In the first section (Privacy Statement), respondents agree to the research study obtaining their personal data. The second section (Personal Information) requests demographics. This was aimed at assessing age, gender, and experience. Data were analyzed using PLS-SEM. SEM is more useful than other research methods in modeling latent variables, accounting for measurement errors, and evaluating complete theories. Measurement and structural models are evaluated empirically. The data can tell us how well the theory fits the data.

To achieve this, the scholars performed evaluations of reflective and formative measurement models. Reflective measurement models are evaluated for indicator and construct reliability. The average variance extracted (AVE) is used to assess each measure's convergent validity. It also allows comparison of a reflectively measured construct to other construct measures in the same model using the heterotrait–monotrait (HTMT) correlation ratio. [17]. The following were performed for evaluation: 1) Assess the indicator reliability by determining outer loading above 0.70, particularly with loadings above 0.708 or higher are recommended to be considered as acceptable item reliability [18]. This is because it indicates an indicator's communality that explains 50 percent of its variance; 2) Internal consistency reliability is determined using Cronbach's Alpha and Composite Reliability, which are both statistical measures. Increased values in this metric indicate higher levels of reliability in the data. From satisfactory to good corresponds to the range of values between 0.70 and 0.90; 3) By looking at the average variance extracted (AVE) for all indicators on a construct, you can figure out how good the Convergent Validity is. AVEs with a value of 0.50 or more are acceptable. An AVE of 0.50 or more shows that the construct is responsible for 50 percent or more of all the variance in the indicators. and 4) Assess the Discriminant Validity through Fornell-Larcker criterion or HTMT ratio and examination of cross-loadings. With an HTMT value less than 0.90, discriminant validity between two reflective constructs has been established.

Validity through Fornell-Larcker criterion or HTMT ratio and examination of cross-loadings. With an HTMT value less than 0.90, discriminant validity between two reflective constructs has been established.

IV. RESULTS

A look at the demographics of the respondents who took part in this study showed that most of them were male. Of the 51 respondents who participated in the study, 55 percent were male and 45 percent were female.

A. Model Evaluation

Before assessing the model, the researcher confirms that the estimation is technically correct and that no Heywood

Authorized licensed use limited to: Technological Inst of the Philippines. Downloaded on May 23,2023 at 09:58:04 UTC from IEEE Xplore. Restrictions apply.

TABLE I
RESEARCH MODEL: THE DEMOGRAPHICS OF THE PEOPLE WHO ANSWERED THE SURVEY

Variable	N(%)	
Gender	Male	28 (55%)
	Female	23 (45%)
Age (years old)	22-27	14 (27.45%)
	28-33	21 (47.05%)
	34-39	2 (3.92%)
	40 and above	14 (27.45%)

cases were found. [19]. Data were assessed and analyzed using different approach to confirm its reliability and validity. A confirmatory factor analysis was done to see how the items in the questionnaire measured the relationship between the latent and observed variables. The model developed in this study examines the inter-relationship between PE, EE, SI, FC, HM, HB, BI, and UB. The model is illustrated in Figure 3. Table 2 includes measurement and structural model evaluation. Measurement model evaluates construct validity and reliability; structural model examines variable relationships. Inner weighting employed factor weighting, and statistical inferences using 10,000 bootstrap subsamples.

The research model used in this study is depicted in Figure 3. This model employs the UTAUT2 model in its entirety, excluding the moderating factors. This procedure enables us to determine whether the model is suitable for further investigation by examining its reliability and validity using different approaches such as Cronbach's alpha, rhoA, Composite Reliability, and Average Variance Extracted (AVE). The Fornell-Larcker Criterion, Cross-loadings, and the Heterotrait–Monotrait (HTMT) Ratio also show that the model is either acceptable or not.

B. Data Results and Analysis

1) Measurement Model: The relationship between constructs and indicator variables can be deduced from measurement models. The measurement model's evaluation removed indicators with low factor loadings (0.70). Low factor loading removed ten (10) factors, including: (PE1, HB2, FC1, FC4, UB1, UB2, UB3, UB4, UB6, and UB9). The measurement model starts with a reliability analysis, which includes composite reliability. Composite reliability should be at least 0.70. As a result, all latent constructs in the model have composite reliability (Table 2). The model also has convergent validity. Presented in Table 2 the Average Variance Extracted (AVE) is used to measure convergent validity in this study; the value must be greater than 0.50 to be accepted as proof of convergent validity. The constructs in this model have a lot of credibility. Also in the same table, Convergent validity exists for the constructs in this model. The Heterotrait Monotrait (HTMT) Ratio procedure is used to determine the discriminant validity of the constructs. According to Henseler [19], [20], when determining whether discriminant validity exists, the most conservative threshold for the HTMT ratio is less than or equal to 0.90. In accordance with the findings of this study, which are presented in Table 3, all HTMT values are less than the threshold value of 0.90. As a result of this procedure, discriminant validity is achieved.

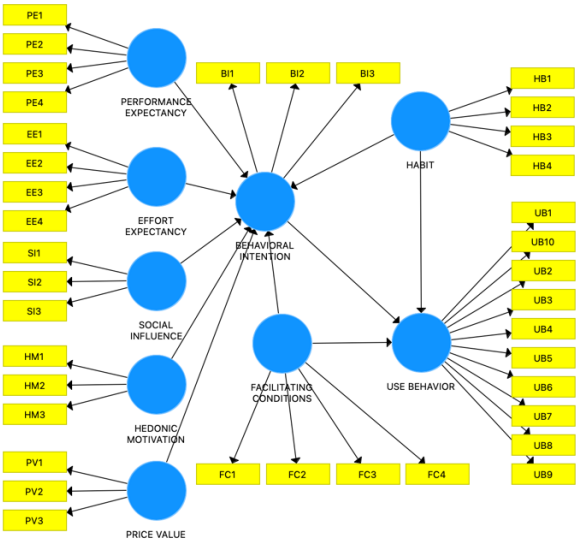

Fig. 3. Research Model

2) Structural Model: It depicts the hypothesized relationships or paths between the constructs in the study model, which are represented by the structural model. The R2, Q2, and significance of paths are used to evaluate a structural model. The strength of each structural path, as determined by the R2 value for the dependent variable, determines the goodness of the model. [21], For the variance explained by a particular endogenous construct to be considered adequate, the value for R2 must be equal to or greater than 0.1 [22]. Subsequently, to aggregate its results, Hair et al. [18], [23] suggested in scholarly research, Endogenous latent variable R2 values of 0.75, 0.50, or 0.25 are considered substantial, moderate, or weak, respectively.

Table 4 shows that all R2 values are above 0.1. Q2 establish the endogenous constructs' predictive relevance. The same table shows that the constructs can be predicted and indicates predictive relevance with its Q2 value above zero (0). SRMR was also used to assess model fit. Even though the SRMR value was 0.080, and was below the required 0.10 value, it still considered acceptable model fit. [24]. Further assessment of the goodness of fit, hypotheses were tested to establish the significance of the relationship. Referring to the established research hypothesis, using Table 4, all hypotheses are positively supported. This means that H1 to H9 evaluates their counterparts constructs directly and positively affect both behavioral intentions and use behavior.

H1 evaluates whether **PE** directly and positively affects **BI**. Assuming the total effect of **PE** on **BI** (β = *0.040, t = 0.168, p = 0.866*), the results supported **H1**. **H2** evaluates whether **EE** directly and positively affects **BI**. Assuming the total effect of **EE** on **BI** (β = *0.008, t = 0.027, p = 0.979*), the results supported **H2**. **H3** evaluates whether **SI** directly and positively affects **BI**. Assuming the total effect of **SI** on **BI** (β = *0.049, t = 0.187, p = 0.852*), the results supported **H3**. **H4** evaluates whether **FC** directly and positively affects **UB**. Assuming the total effect of **FC** on **UB** (β = *0.158, t = 0.187, p = 0.387*), the results supported **H4**. **H5** evaluates whether **FC** directly and positively affects **BI**. Assuming the total effect of **FC** on **BI** (β = *0.020, t = 0.076, p = 0.378*), the results supported **H5**. **H6** evaluates whether **HM** directly and positively affects **BI**. Assuming the total effect of **HM** on **BI** (β = *0.350, t = 1.440., p = 0.150*), the results supported **H6**. **H7** evaluates whether **HB** directly and positively affects **BI**. Assuming the total effect of **HB** on **BI** (β = *0.325, t = 1.300, p = 0.194*), the results supported **H7**. **H8** evaluates whether **HB** directly and positively affects **UB**. Assuming the total effect of **HB** on **UB** (β = *0.241, t = 1.530, p = 0.126*), the results supported **H8**. **H9** evaluates whether **BI** directly and positively affects **UB**. Assuming the total effect of **BI** on **UB** (β = *0.158, t = 0.951, p = 0.341*), the results supported **H9**.

As can be seen in Table 4, bootstrapping with 10,000 resamples was used to assess the model's statistical significance [17], [23], [24]. This generated 97.5 percent confidence intervals. A significant relationship exists when the confidence interval is greater than or equal to zero (0). Table 4 summarizes the results of the hypothesis testing.

3) Moderation Analysis: Moderation Analysis was performed to evaluate age as moderator on the following relationships between: PE BI; EE → BI; SI → BI; and FC → UB.

Authorized licensed use limited to: Technological Inst of the Philippines. Downloaded on May 23,2023 at 09:58:04 UTC from IEEE Xplore. Restrictions apply.

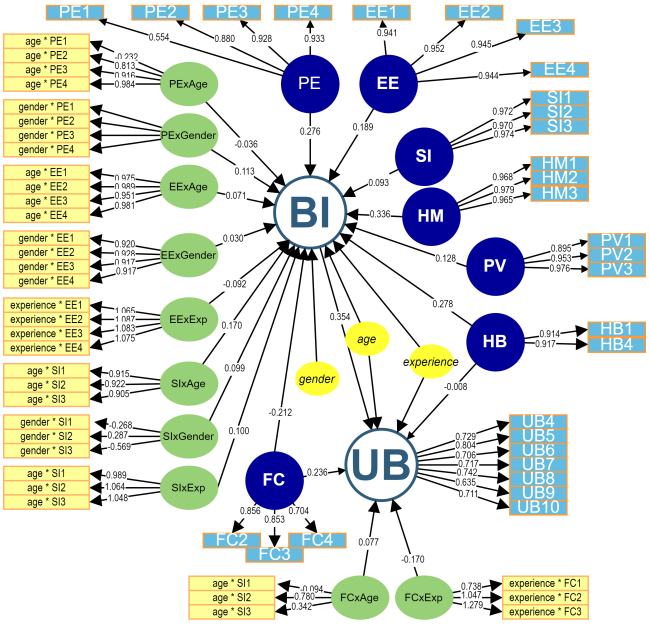

Fig. 4. Model Results for Learning Management System as a Blended Workplace Using the research model

The results revealed a significant moderation of age for EE and BI (β = 0.302, t = 1.127, p = 0.260); and FC and UB (β = 0.084, t = 0.421, p = 0.674). As to other constructs (PE $\rightarrow$ BI, SI $\rightarrow$ BI), results revealed insignificant moderation of age (see Table 5). Gender as moderator, results revealed that only PE $\rightarrow$ BI (β = 0.236, t = 1.167, p = 0.243) revealed a significant moderation. The other two relationships: EE $\rightarrow$ BI and SI $\rightarrow$ BI revealed insignificant moderation of age. Experience as moderator, results revealed that only SI $\rightarrow$ BI (β = 0.162, t = 0.620, p = 0.535) revealed a significant moderation. The other two relationships: EE $\rightarrow$ BI and FC $\rightarrow$ UB revealed insignificant moderation of experience. Hence, the results of the bootstrapped, it showed in 97.5 confidence interval that all moderators significantly moderate all factors.

V. DISCUSSIONS

This study removed Price Value from the UTAUT2 Model since the LMS is free for users. Adopting a study framework allows scholars to verify the viability of an LMS as a blended workplace application. All hypotheses were supported without age, gender, or experience. According to the questionnaire variables used to quantify Performance Expectancy, the online application helps them become more productive, eliminate slack, and provide better service to the college. These were considered in this measure: 1) they find the web application useful in their daily life; 2) using the web application increases their chances of achieving deadlines that are important to them; 3) using the web application helps them to accomplish tasks more quickly; and lastly, 4) using the web application increases their productivity. Since ParSU previously used Google Classroom, effort expectancy were established. Apart from this, there were numerous trainings conducted to support the transition. As to Effort Expectancy, based on the questionnaire, respondents shared the same thoughts of learning to use the Moodle LMS for instruction and as a blended workplace is easy to them. Their interaction with the application is clear and understood. Moreover, they find the application easy to use and it allows them to become skillful at using the web application. The social influence is effective because they are compelled to use the application on the work under the supervision and influence of their immediate supervisor and coworkers. This effect motivates them to adopt the technology as well. Finally, their subscription to technology is influenced by their subordinates and those whose opinions matter and are held in high regard by them. UTAUT2 model incorporated hedonic motivation to determine how well users are coping with the technology. The hypothesis was supported that using the application allows them to enjoy work and be entertained. Additionally, the web application enables users to adjust their behavior when interacting with the application. Notably, because required quality assurance documents such as test questions, syllabus, table of specifications, course outlines, and other supporting documents are critical for ISO certification and program accreditation, this application educated them about the benefits of using it for this purpose. Utilizing the web application became second nature to them.

VI. CONCLUSION

Because this paper demonstrated that it is possible to use the LMS as a blended workplace application, to assist a university in adapting to the new normal, particularly in quality assurance activities, it is highly recommended that the platform be used for a university-wide implementation of the platform. Furthermore, if an educational institution is applying for international standard certification or program accreditation, a learning management system (LMS), particularly Moodle, can be of great assistance in maintaining administrative works, submission, reviewing, approving, and monitoring of required documents.
